

Email Sender Using Node Js

The email sender project is a web application built using Node.js and the nodemailer module. It allows users to send emails from their own email address to any recipient. Users can enter their email address, password, recipient's email address, subject, and message. The application then uses nodemailer to send the email through the SMTP server. If the email is sent successfully, the user is redirected to a success page, and if there is an error, the user is redirected to 500 error page. Overall, the project provides a simple and efficient way for users to send emails from their own email address using Node.js and nodemailer.
